Abstract

Let M to be a matroid defined on a finite set E and $L \subset E$. L is locked in M if $M|L$ and $M^*(E \setminus L)$ are 2-connected, and $\min\{r(L), r^*(E \setminus L)\} \geq 2$. Given a positive integer k , M is k -locked if the number of its locked subsets is $O(|E|^k)$. \mathcal{L}_k is the class of k -locked matroids (for a fixed k). In this paper, we give a new axiom system for matroids based on locked subsets. We deduce that the matroid isomorphism problem (MIP) for \mathcal{L}_k is polynomially time reducible to the graph isomorphism problem (GIP). \mathcal{L}_k is closed under 2-sums and contains the class of uniform matroids, the Vámos matroid and all the excluded minors of 2-sums of uniform matroids. MIP is coNP-hard even for linear matroids.

2010 Mathematics Subject Classification: Primary 05B35, Secondary 90C27, 52B40.

Key words and phrases: locked subsets, matroid isomorphism, graph isomorphism, self duality, polynomially locked matroid.

1 Introduction

Sets and their characterisitic vectors will not be distinguished. We refer to Oxley [6] and Schrijver [9] about matroids and polyhedra terminolgy and facts, respectively.

Given two matroids M_1 and M_2 , the Matroid Isomorphism Problem (MIP) is to find a bijection $\varphi : E(M_1) \rightarrow E(M_2)$ such that the class of bases of both matroids $\mathcal{B}(M_1)$ and $\mathcal{B}(M_2)$ are isomorphic, i.e., for any base $B_1 \in \mathcal{B}(M_1)$ there exists a unique base $B_2 \in \mathcal{B}(M_2)$ such that $\varphi(B_1) = B_2$. This problem is in Σ_2^P [7]. Even for linear matroids, MIP is in Σ_2^P -complete and coNP-hard [7]. For matroids and

linear matroids with matroid rank bounded by a constant, MIP is polynomially time equivalent to the Graph Isomorphism Problem (GIP)[7]. Nonsuccinct approaches of MIP has been studied in [5]: MIP is GI-complete if we use the list of all independent sets (for example) in the input instead of a matroid oracle to access the matroid. Unfortunately, this approach requires an exponential input size (see [8]) and then an exponential time on the size of $|E|$. In this paper, we prove that MIP is reducible to Graph Isomorphism Problem for a large class of matroids denoted \mathcal{L}_k . This class is closed under 2-sums and contains the class of uniform matroids, the Vámos matroid and all the excluded minors of 2-sums of uniform matroids, i.e., $M(K_4)$, W^3 , Q_6 and P_6 [2]. It follows that this class contains strictly 2-sums of uniform matroids.

Let's give some definitions. Given a matroid M defined on a finite set E . Suppose that M (and M^*) is 2-connected. A subset $L \subset E$ is called a locked subset of M if $M|L$ and $M^*|(E \setminus L)$ are 2-connected, and their corresponding ranks are at least 2, i.e., $\min\{r(L), r^*(E \setminus L)\} \geq 2$. It is not difficult to see that if L is locked then both L and $E \setminus L$ are closed, respectively, in M and M^* (That is why we call them locked). We denote by $\mathcal{L}(M)$ and $\ell(M)$, respectively, the class of locked subsets of M and its cardinality, which is called the locked number of M . Given a positive integer k (k does not depend on M or $|E|$), we say that M is k -locked if $\ell(M) \in O(|E|^k)$. \mathcal{L}_k is the class of k -locked matroids. M is 0-locked if $\mathcal{L}(M) = \emptyset$, i.e., $\ell(M) = 0$ and the class of such matroids is \mathcal{L}_0 . For a given nonnegative integer k , \mathcal{L}_k is called also a polynomially locked class of matroids. It is not difficult to see that the class of locked subsets of a matroid M is the union of locked subsets of the 2-connected components of M . The locked structure of M is the quadruple $(\mathcal{P}(M), \mathcal{S}(M), \mathcal{L}(M), \rho)$, where $\mathcal{P}(M)$ and $\mathcal{S}(M)$ are, respectively, the class of parallel and coparallel closures, and ρ is the rank function restricted to $\mathcal{P}(M) \cup \mathcal{S}(M) \cup \mathcal{L}(M) \cup \{\emptyset, E\}$.

A matroid can be completely characterized by its locked structure through its bases polytope [3]. We will give in this paper a new axiom system for defining matroids based on this quadruple.

The remainder of this paper is organized as follows. In section 2, we give a new axiom system for defining matroids, then, in section 3, we prove that MIP is polynomially time reducible to GI for polynomially locked classes of matroids, and give some large classes of such classes of matroids. Finally, we will conclude in section 4.

2 The Locked Axioms for a Matroid

Given a finite set E , $M = (E, \mathcal{P}, \mathcal{S}, \mathcal{L}, r)$ is a locked system defined on E if:

- (L1) $E \neq \emptyset$,
- (L2) \mathcal{P} and \mathcal{S} are partitions of E ,
- (L3) For any $(P, S) \in \mathcal{P} \times \mathcal{S}$, if $P \cap S \neq \emptyset$ then $|P| = 1$ or $|S| = 1$,
- (L4) \mathcal{L} is a class of nonempty and proper subsets of E such that $\mathcal{L} \cap \mathcal{P} = \mathcal{L} \cap \mathcal{S} = \emptyset$,
- (L5) For any $(X, L) \in (\mathcal{P} \cup \mathcal{S}) \times \mathcal{L}$, $X \cap L = \emptyset$ or $X \subset L$,

- (L6) r is a nonnegative function defined on 2^E ,
- (L7) $r(\emptyset) = 0$ and $r(E) \geq r(X)$ for any $X \subseteq E$,
- (L8) $r(P) = \min\{1, r(E)\}$ for any $P \in \mathcal{P}$,
- (L9) $r(E \setminus P) = \min\{|E \setminus P|, r(E)\}$ for any $P \in \mathcal{P}$,
- (L10) $r(S) = \min\{|S|, r(E)\}$ for any $S \in \mathcal{S}$,
- (L11) $r(E \setminus S) = \min\{|E \setminus S|, r(E) + 1 - |S|\}$ for any $S \in \mathcal{S}$,
- (L12) $r(L) \geq \max\{2, r(E) + 2 - |E \setminus L|\}$ for any $L \in \mathcal{L}$,
- (L13) r is increasing on $\mathcal{P} \cup \mathcal{L} \cup \{\emptyset, E\}$,
- (L14) r is submodular on $\mathcal{P} \cup \mathcal{S} \cup \mathcal{L} \cup \{\emptyset, E\}$,
- (L15) For any $L \in \mathcal{L}$, if $L = X \cup Y$ and $X \cap Y = \emptyset$ then $r(L) < r(X) + r(Y)$,
- (L16) For any $L \in \mathcal{L}$, if $L = X \cap Y$ and $X \cup Y = E$ then $r(L) < r(X) + r(Y) - r(E)$,
- (L17) For any $X \notin \mathcal{P} \cup \mathcal{S} \cup \mathcal{L} \cup \{\emptyset, E\}$, one of the following holds:

(P1) There exists $L \in \mathcal{L}$ such that $L \subset X$, $r(X) = r(L) + r(X \setminus L)$, and $X \setminus L$ verifies (P1) or (P2),

(P2) There exists $P \in \mathcal{P}$ such that $P \cap X \neq \emptyset$, $r(X) = r(P) + r(X \setminus P)$, and $X \setminus P$ verifies (P1) or (P2),

(P3) There exists $L \in \mathcal{L}$ such that $X \subset L$, $r(X) = r(L) + r(X \cup (E \setminus L)) - r(E)$, and $X \cup (E \setminus L)$ verifies (P3) or (P4),

(P4) There exists $S \in \mathcal{S}$ such that $(E \setminus S) \cup X \neq E$, $r(X) = r(E \setminus S) + r(X \cup S) + |S \cap X| - r(E)$, and $X \cup S$ verifies (P3) or (P4),

(L18) For any $(L_1, L_2) \in \mathcal{L}^2$, if $L_1 \cap L_2 \neq \emptyset$ and $L_1 \cap L_2 \notin \mathcal{L}$ then $L_1 \cap L_2$ verifies (P1) or (P2) of (L17),

(L19) For any $(L_1, L_2) \in \mathcal{L}^2$, if $L_1 \cup L_2 \neq E$ and $L_1 \cup L_2 \notin \mathcal{L}$ then $L_1 \cup L_2$ verifies (P3) or (P4) of (L17),

Note that the axiom (L17) gives a way on how to compute the values of the function r outside $\mathcal{P} \cup \mathcal{S} \cup \mathcal{L} \cup \{\emptyset, E\}$. So we do not need to verify it for a locked system realization. Note also that some axioms will not be used partially or completely later but were introduced in order to define a dual system if needed. Without loss of generality, we can replace axioms (L8)-(L11) by the following axioms respectively:

- (LL8) $r(P) = 1$ for any $P \in \mathcal{P}$,
- (LL9) $r(E \setminus P) = r(E)$ for any $P \in \mathcal{P}$,
- (LL10) $r(S) = |S|$ for any $S \in \mathcal{S}$,
- (LL11) $r(E \setminus S) = r(E) + 1 - |S|$ for any $S \in \mathcal{S}$.

Let's give the following polyhedra associated to the locked system M :

$P(M)$ is the set of all $x \in R^E$ satisfying the following inequalities:

$$x(E) = r(E) \tag{1}$$

$$x(P) \leq 1 \text{ for any } P \in \mathcal{P} \tag{2}$$

$$x(S) \geq |S| - 1 \text{ for any } S \in \mathcal{S} \quad (3)$$

$$x(L) \leq r(L) \text{ for any } L \in \mathcal{L} \quad (4)$$

Now, we can start our process to prove the main theorem.

Lemma 2.1. *If $x \in P(M)$ then*

$$0 \leq x(e) \leq 1 \text{ for any } e \in E \quad (5)$$

Proof. Let $e \in E$. Since \mathcal{P} and \mathcal{S} are partitions of E (L2) then there exist a pair $(P, S) \in \mathcal{P} \times \mathcal{S}$ such that $\{e\} = P \cap S$ (L3).

Case 1: if $|P| = |S| = 1$ then inequalities (2) and (3) imply inequalities (5).

Case 2: if $|S| \geq 2$ then $\{f\} \in \mathcal{P}$ for any $f \in S$ (L3). Inequalities (2) imply $x(f) \leq 1$ for any $f \in S$. In particular $x(e) \leq 1$. It follows that $x(S \setminus \{e\}) \leq |S| - 1$, then $x(e) = x(S) - x(S \setminus \{e\}) \geq (|S| - 1) - (|S| - 1) = 0$

Case 3: if $|P| \geq 2$ then $\{f\} \in \mathcal{S}$ for any $f \in P$ (L3). Inequalities (3) imply $x(f) \geq 0$ for any $f \in P$. In particular $x(e) \geq 0$. It follows that $x(P \setminus \{e\}) \geq 0$, then $x(e) = x(P) - x(P \setminus \{e\}) \leq x(P) \leq 1$. \square

Lemma 2.2. *If $x \in P(M)$ then*

$$x(A) \leq r(A) \text{ for any } A \subseteq E \quad (6)$$

Proof. We have the following cases:

Case 1: if $A = \emptyset$ then $x(A) = 0 \leq 0 = r(A)$ (L7).

Case 2: if $A = E$ then $x(A) = r(A) \leq r(A)$ (inequality 1).

Case 3: if $A \in \mathcal{P}$ then $x(A) \leq 1 = r(A)$ (inequality 2 and LL8).

Case 4: if $A \in \mathcal{S}$ then $x(A) \leq |A| = r(A)$ (Lemma 2.1 and LL10).

Case 5: if $E \setminus A \in \mathcal{S}$ then $x(A) = x(E) - x(E \setminus A) \leq r(E) - |E \setminus A| + 1 = r(A)$ (inequality 3 and LL11).

Case 6: if $A \notin \mathcal{P} \cup \mathcal{S} \cup \mathcal{L} \cup \{\emptyset, E\}$ and $E \setminus A \notin \mathcal{S}$ then the axiom (L17) implies one of the following subcases:

Subcase 6.1: There exists $L \in \mathcal{L}$ such that $L \subset A$, $r(A) = r(L) + r(A \setminus L)$, and $A \setminus L$ verifies (P1) or (P2). So by induction on $|A|$, $x(A) = x(L) + x(A \setminus L) \leq r(L) + r(A \setminus L) = r(A)$ because $|A \setminus L| < |A|$ and inequality 4.

Subcase 6.2: There exists $P \in \mathcal{P}$ such that $P \cap A \neq \emptyset$, $r(A) = r(P) + r(A \setminus P)$, and $A \setminus P$ verifies (P1) or (P2). So by induction on $|A|$, $x(A) \leq x(P) + x(A \setminus P) \leq r(P) + r(A \setminus P) = r(A)$ because $|A \setminus P| < |A|$, Lemma 2.1 and Case 3,

Subcase 6.3: There exists $L \in \mathcal{L}$ such that $A \subset L$, $r(A) = r(L) + r(A \cup (E \setminus L)) - r(E)$, and $A \cup (E \setminus L)$ verifies (P3) or (P4). So by induction on $|E \setminus A|$, $x(A) = x(L) + x(A \cup (E \setminus L)) - x(E) \leq r(L) + r(A \cup (E \setminus L)) - r(E) = r(A)$ because $|E \setminus (A \cup (E \setminus L))| = |(E \setminus A) \cap L| < |E \setminus A|$ and inequality 4,

Subcase 6.4: There exists $S \in \mathcal{S}$ such that $(E \setminus S) \cup A \neq E$, $r(A) = r(E \setminus S) + r(A \cup S) + |S \cap A| - r(E)$, and $A \cup S$ verifies (P3) or (P4). So by induction on $|E \setminus A|$,

$$x(A) = x((E \setminus S) \cup A) + x(A \cup S) - x(E) \leq r(E \setminus S) + r(A \cup S) + |S \cap A| - r(E) = r(A)$$

because $|E \setminus (A \cup S)| = |(E \setminus A) \cap (E \setminus S)| < |E \setminus A|$, Lemma 2.1, Case 5, and inequality 4. \square

Let $Q(M)$ be the set of $x \in R^E$ such that x verifies the inequalities (1), (5) and (6).

Corollary 2.3. $P(M) = Q(M)$.

Proof. Lemma 2.1 and 2.2 imply that $P(M) \subseteq Q(M)$. We need to prove the inverse inclusion. Let $x \in Q(M)$. It is clear that x verifies the inequalities (2) and (4) by using inequality (6) and axiom (LL8). Let $S \in \mathcal{S}$ then, by using inequalities (1), (6) and axiom (LL11), $x(S) = x(E) - x(E \setminus S) \geq r(E) - r(E \setminus S) = r(E) - r(E) - 1 + |S| = |S| - 1$, which is inequality (3). \square

Lemma 2.4. Let $x \in P(M)$ such that $x(L_i) = r(L_i)$, for some $L_i \in \mathcal{L}, i = 1, 2$. If $L_1 \cap L_2 \neq \emptyset$ then there exists $L \in \mathcal{P} \cup \mathcal{L}$ such that $L \subseteq L_1 \cap L_2$ and $x(L) = r(L)$.

Proof. By using Lemma 2.2 and axiom (L14), we have:

$$r(L_1) + r(L_2) = x(L_1) + x(L_2) = x(L_1 \cap L_2) + x(L_1 \cup L_2) \leq r(L_1 \cap L_2) + r(L_1 \cup L_2) \leq r(L_1) + r(L_2).$$

It follows that $x(L_1 \cap L_2) = r(L_1 \cap L_2)$ and $x(L_1 \cup L_2) = r(L_1 \cup L_2)$.

If $L_1 \cap L_2 \in \mathcal{L}$ then $L = L_1 \cap L_2$.

Otherwise, by using axiom (L18), we have two cases:

Case 1: There exists $L \in \mathcal{L}$ such that $L \subset L_1 \cap L_2$, $r(L_1 \cap L_2) = r(L) + r((L_1 \cap L_2) \setminus L)$, and $(L_1 \cap L_2) \setminus L$ verifies (P1) or (P2) of axiom (L17). It is not difficult to see, by a similar argument as hereabove, that $x(L) = r(L)$ and $x((L_1 \cap L_2) \setminus L) = r((L_1 \cap L_2) \setminus L)$.

Case 2: There exists $P \in \mathcal{P}$ such that $P \cap (L_1 \cap L_2) \neq \emptyset$, $r(L_1 \cap L_2) = r(P) + r((L_1 \cap L_2) \setminus P)$, and $(L_1 \cap L_2) \setminus P$ verifies (P1) or (P2) of axiom (L17). Axiom (L5) implies that $P \subseteq L_1 \cap L_2$. It is not difficult to see, by a similar argument as hereabove, that $x(P) = r(P)$ and $x((L_1 \cap L_2) \setminus P) = r((L_1 \cap L_2) \setminus P)$. \square

Theorem 2.5. $P(M)$ is integral.

Proof. Let $x \in P(M)$ be a fractional extreme point and $F = \{g \in E \text{ such that } 0 < x(g) < 1\}$. Since x is fractional and $x(E) = r(E)$ is integral then $|F| \geq 2$.

Let $\mathcal{P}_x = \{P \in \mathcal{P} \text{ such that } x(P) = 1\}$, $\mathcal{S}_x = \{S \in \mathcal{S} \text{ such that } x(S) = |S| - 1\}$, and $\mathcal{L}_x = \{L \in \mathcal{L} \text{ such that } x(L) = r(L)\}$, i.e., the corresponding tight inequalities of x .

Case 1: There exists $X \in \mathcal{P} \cup \mathcal{S}$ such that $|X \cap F| \geq 2$. Let $\{e, f\} \subseteq X \cap F$. It

follows that there exists $\varepsilon > 0$ such that $0 < x(e) - \varepsilon < 1$ and $0 < x(f) + \varepsilon < 1$. Let $x_\varepsilon \in R^E$ such that:

$$x_\varepsilon(g) = \begin{cases} x(g) & \text{if } g \notin \{e, f\}; \\ x(e) - \varepsilon & \text{if } g = e; \\ x(f) + \varepsilon & \text{if } g = f. \end{cases}$$

It is clear that $x_\varepsilon(E) = r(E)$. Axioms (L2), (L3) and (L5) imply that $\mathcal{P}_x = \mathcal{P}_{x_\varepsilon}$, $\mathcal{S}_x = \mathcal{S}_{x_\varepsilon}$, and $\mathcal{L}_x = \mathcal{L}_{x_\varepsilon}$, i.e., x_ε verifies the same tight constraints as x , a contradiction.

Case 2: For any $X \in \mathcal{P} \cup \mathcal{S}$, we have $|X \cap F| \leq 1$. It follows that for any $X \in \mathcal{P}_x \cup \mathcal{S}_x$, we have $X \cap F = \emptyset$.

Subcase 2.1: There exists $L \in \mathcal{L}_x$ such that $|L \cap F| \geq 2$, and $\{e, f\} \subseteq L \cap F$ such that if $L' \in \mathcal{L}_x$ then $\{e, f\} \subseteq L'$ or $\{e, f\} \cap L' = \emptyset$. So we proceed as in Case 1 and we conclude.

Subcase 2.2: For any $L \in \mathcal{L}_x$ such that $|L \cap F| \geq 2$, and any $\{e, f\} \subseteq L \cap F$, there exists $L' \in \mathcal{L}_x$ such that $|\{e, f\} \cap L'| = 1$. Suppose that $f \in L'$. So we have:

$$r(L) + r(L') = x(L) + x(L') = x(L \cap L') + x(L \cup L') \leq r(L \cap L') + r(L \cup L') \leq r(L) + r(L').$$

It follows that $x(L \cap L') = r(L \cap L')$ and $x(L \cup L') = r(L \cup L')$. It follows that $|L \cap L' \cap F| \geq 2$.

By using Lemma 2.4, and since $L \cap L' \neq \emptyset$ then there exists $X \in \mathcal{P} \cup \mathcal{L}$ such that $X \subseteq L \cap L'$ and $x(X) = r(X)$. By induction on $|L \cap L'|$, we have $X \cap F \neq \emptyset$ (otherwise we do the same for $(L_1 \cap L_2) \setminus X$), i.e., $|X \cap F| \geq 2$. Induction on $|L|$ and axiom (L13) imply that $r(X) = 1$, i.e., $X \in \mathcal{P}$, a contradiction. \square

Now we can state our main theorem as follows.

Theorem 2.6. *The extreme points of $P(M)$ are the bases of a matroid defined on E , and $\mathcal{P}, \mathcal{S}, \mathcal{L}, r$ are, respectively, the class of parallel and coparallel closures, locked subsets and rank function of this matroid.*

Proof. Lemma 2.1 and Theorem 2.5 imply that the extreme points of $P(M)$ are in $\{0, 1\}^E$. We remind here that we will not distinguish between sets and $\{0, 1\}$ -vectors. Inequality (1) implies that extreme points of $P(M)$ have the same cardinality $r(E)$. We only need to prove the basis exchange axiom. We will do it by contradiction. Let x and x' to be two extreme points of $P(M)$ and $e \in x \setminus x'$ such that for any $f \in x' \setminus x$, $x - e + f$ is not an extreme point, i.e., $x - e + f \notin P(M)$. It is clear that $|x' \setminus x| \geq 2$. Let $x_f = x - e + f$.

Case 1: x_f violates an inequality of type (2), i.e., there exists $P_f \in \mathcal{P}$ such that $x_f(P_f) \geq 2$. It follows that $e \notin P_f$, $f \in P_f$, $x(P_f) = 1$, and $x_f(P_f) = 2$. Thus there exists $f' \in P_f \cap x_f \cap x$ such that $f' \neq f$.

Claim: If $f_1 \neq f_2$ then $f'_1 \neq f'_2$.

Suppose, by contradiction, that $f' = f'_1 = f'_2$. Since $f' \in P_{f_i} \cap x_{f_i}$, $i = 1, 2$, then $f' \in P_{f_1} \cap P_{f_2}$. Axiom (L2) implies that $P_{f_1} = P_{f_2} = P$ and $\{f_1, f_2\} \subseteq P \cap x'$. It

follows that $x'(P) \geq 2$, a contradiction.

Since $|x \setminus x'| = |x' \setminus x|$ then $x \setminus x' = \bigcup_{i=1}^{|x \setminus x'|} \{f'_i\} \subseteq \bigcup_{i=1}^{|x \setminus x'|} P_{f_i}$ but $e \notin P_{f_i}, i = 1, 2, \dots, |x \setminus x'|$, a contradiction.

Case 2: x_f violates an inequality of type (3), i.e., there exists $S_f \in \mathcal{S}$ such that $x_f(S_f) \leq |S| - 2$. It follows that $e \in S_f$, $f \notin S_f$, $x(S_f) = |S_f| - 1$, and $x_f(S_f) = |S_f| - 2$. Since $e \in S_f$ for any $f \in x' \setminus x$, and by using axiom (L2), we have $S_f = S$, i.e., for distinct f_1 and f_2 , $S_{f_1} = S_{f_2} = S$. It follows that $(x' \setminus x) \cap S = \emptyset$. But $x'(S) \geq |S| - 1$ because $x' \in P(M)$, then $(x' \cap x)(S) \geq |S| - 1$. It follows that $(x \setminus x') \cap S = \emptyset$, a contradiction with $e \in S$.

Case 3: x_f violates an inequality of type (4), i.e., there exists $L_f \in \mathcal{L}$ such that $x_f(L_f) \geq r(L_f) + 1$. It follows that $e \notin L_f$, $f \in L_f$, $x(L_f) = r(L_f)$, and $x_f(L_f) = r(L_f) + 1$. We choose L_f maximal for this property.

Subcase 3.1: There are $f_1 \neq f_2$ such that $x_{f_1}(L_{f_2}) = r(L_{f_2})$, i.e., $f_1 \notin L_{f_2}$.

As shown in the proof of Lemma 2.4, $x(L_{f_1} \cup (L_{f_2})) = r(L_{f_1} \cup (L_{f_2}))$. Since L_{f_2} is maximal then $L_{f_1} \cup L_{f_2} \notin \mathcal{L}$. Since $e \notin L_{f_1} \cup L_{f_2}$, and by using axiom (L19), there exists $S \in \mathcal{S}$ such that $(E \setminus S) \cup (L_{f_1} \cup L_{f_2}) \neq E$, $r(L_{f_1} \cup L_{f_2}) = r(E \setminus S) + r(L_{f_1} \cup L_{f_2} \cup S) + |S \cap (L_{f_1} \cup L_{f_2})| - r(E)$, and $(L_{f_1} \cup L_{f_2}) \cup S$ verifies (P4) (property (P3) cannot be verified because of maximality of L_{f_2}). By a similar argument as in the proof of Lemma 2.4, we have:

(1) $x(E \setminus S) = r(E \setminus S)$ which imply that $x(S) = |S| - 1$, i.e., $S = x \setminus \{e'\} \cup \{f'\}$ for some $e' \in x$ and $f' \notin x$,

and (2) $x(L_{f_1} \cup L_{f_2} \cup S) = r(L_{f_1} \cup L_{f_2} \cup S)$.

If $e \in S$ (i.e. $e \neq e'$) then at least one the $x_{f_i}(S) = |S| - 2$ (i.e. $f_i \neq f'$) and we are in Case 2). Else $e \notin S$, i.e. $e \notin L_{f_1} \cup L_{f_2} \cup S$ and by induction on $|E \setminus X|$ where $X = L_{f_1} \cup L_{f_2}$, we get a contradiction.

Subcase 3.2: For any $f_1 \neq f_2$, $x_{f_1}(L_{f_2}) = r(L_{f_2}) + 1$, i.e., $f_1 \in L_{f_2}$. It follows that there exists $L \in \mathcal{L}$ such that $x' \setminus x \subseteq L$, $e \notin L$, and $x(L) = r(L)$. We have then:

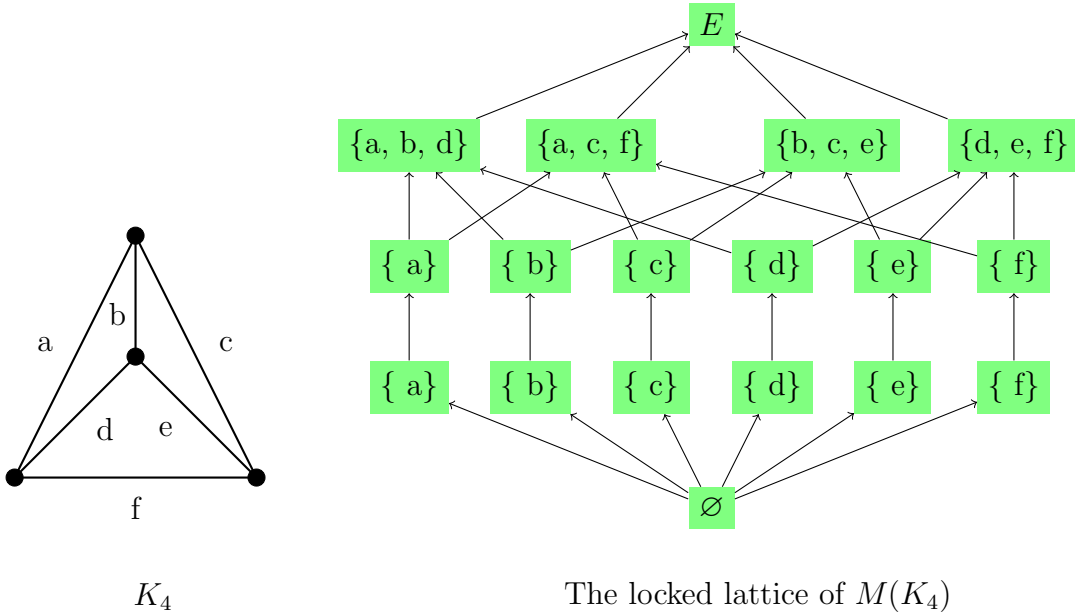

$r(L) \geq x'(L) = (x' \setminus x)(L) + (x' \cap x)(L) = |x' \setminus x| + (x' \cap x)(L) = |x \setminus x'| + (x' \cap x)(L) \geq (x \setminus x')(L) + (x' \cap x)(L) = x(L) = r(L)$. It follows that $(x \setminus x')(L) = |x \setminus x'|$, i.e., $x \setminus x' \subseteq L$, a contradiction with $e \in x \setminus x'$. \square

Actually this gives a new proof for the bases polytope of a matroid and its facets based on the locked structure only.

3 MIP is reducible to GI for polynomially locked matroids

For any matroid, we can construct an *augmented* lattice of locked subsets vertex-labeled where we add a vertex (representing) for every coparallel closure adjacent to

the root (the empty set) and a vertex (representing) for every parallel closure adjacent to a vertex representing a coparallel closure intersecting this parallel closure. Every vertex is labeled by two numbers: its cardinality and its rank. This lattice is called the locked lattice of this matroid. For example we give herebelow the locked lattice of the graphical matroid $M(K_4)$. The labels are the same for every vertex of a same level. The root (\emptyset , level 0) is labeled with (0, 0); the coparallel (level 1) and parallel closures (level 2) are labeled with (1, 1); the locked subsets (level 3) are labeled with (3, 2); and finally the ground set (E , sink or level 4) is labeled with (6, 3).

It is not difficult to generalize the notion of isomorphism between graphs to directed vertex-labeled graphs. Since the locked structure is completely described by the locked lattice, then we can state the following proposition.

Proposition 3.1. *Two matroids are isomorphic if and only if their corresponding locked lattices are isomorphic.*

We can now reduce the locked lattice to the following. We do not need to label coparallel and parallel closures by their ranks because they are equal, respectively, to the cardinality and 1. We do not need to label any locked subset by its cardinality because it can be computed as the maximum flow from the root to the vertex representing this locked subset in the locked lattice with capacities equal to 1 for arcs between coparallel and parallel closures, and infinity otherwise. This reduced lattice is a directed acyclic vertex-labeled graph and the labels are nonnegative numbers bounded by $|E|$. We call it also the locked lattice of the given matroid. And the previous proposition holds for this locked lattice.

For reducing MIP to GI we need the following theorem [10].

Theorem 3.2. *The Isomorphism Problem in acyclic directed graphs (ADGI) is GI-complete.*

We can now state the main result of this section.

Theorem 3.3. *MIP is polynomial time reducible to GI for polynomially locked classes of matroids.*

Proof. We will reduce isomorphism of locked lattices to ADGI. Consider a matroid M and its locked lattice $L(M)$. If we replace each vertex in $L(M)$ by a number of series arcs equal to its label, then $L(M)$ become an acyclic directed graph without any vertex-labeling. The number of the vertices and the edges in the new graph is bounded, respectively, by $(\ell(M) + 2|E| + 2)(|E| + 1)$ and by $(\ell(M) + 2|E| + 2)^2(|E| + 1)^2$ which is polynomial on the size of the ground set E if M is polynomially locked. \square

The special case in \mathcal{L}_0 is polynomial.

Theorem 3.4. *MIP is polynomial for matroids in \mathcal{L}_0 .*

Proof. Locked lattices in \mathcal{L}_0 are completely described by coparallel and parallel closures. Each of the later forms a partition of the ground set E . Axiom (L3) reduces locked lattices in this case to one level only: coparallel closures (or parallel closures). So locked lattices can be represented by a sequence of at most $|E|$ positive nondecreasing numbers bounded by $|E|$. It is clear that checking numbers of two such sequences will give an answer for MIP in this case. This checking requires a linear running time complexity. \square

Another interesting problem related to MIP is testing self-duality (TSD). Jensen and Korte [4] proved that there exists no polynomial algorithm in which the matroid is represented by an independence test oracle (or an oracle polynomially related to an independence test oracle) for TSD. Chaourar [3] introduced the following matroid oracle which reduces (partially) this question to GI (for polynomially locked classes of matroids).

The k -locked oracle

Input: a nonnegative integer k and a matroid M defined on E .

Output: (1) No if $\ell(M) \notin O(|E|^k)$, and
 (2) $(\mathcal{P}(M), \mathcal{S}(M), \mathcal{L}(M), \rho)$ if $\ell(M) \in O(|E|^k)$.

”Note that this oracle has time complexity $O(|E|^{k+1})$ because we need to count at most $|E|^{k+1}$ members of $\mathcal{L}(M)$ in order to know that M is not k -locked, even if the memory complexity can be $O(|E| + \ell(M))$. Actually this matroid oracle permits to recognize if a given matroid is k -locked or not for a given nonnegative integer k (which does not depend on M or $|E|$)” [3], and this matroid oracle is stronger than the rank and the independence oracles for polynomially locked matroids.

We can now state our second main result for this section.

Corollary 3.5. *TSD is polynomial time reducible to GI for polynomially locked matroids represented by a k -locked oracle.*

Proof. If a matroid M is k -locked for a given nonnegative k (which does not depend on M or $|E|$), then the k -locked oracle gives its locked structure. Since $\mathcal{P}(M^*) = \mathcal{S}(M)$, $\mathcal{S}(M^*) = \mathcal{P}(M)$, $\mathcal{L}(M^*) = \{E \setminus L \text{ such that } L \in \mathcal{L}(M)\}$, $\rho^*(X) = \rho(E \setminus X) + |X| - r(E)$, then $L(M^*)$ can be (computed) constructed in polynomial time from $L(M)$. Since $\ell(M) = \ell(M^*)$ then both matroids are polynomially locked and TSD is reducible to MIP which is reducible to GI. \square

Finally we give some large classes of polynomially locked matroids [1, 2, 3].

Theorem 3.6. *The following properties hold for matroids.*

- (1) *2-sums preserves k -lockdness for a given positive integer k ;*
- (2) *A fixed number of p -sums preserves k -lockdness for positive integers p and k ;*
- (3) *2-sums of uniform matroids are 1-locked;*
- (4) *All matroids on 6 elements are 1-locked, in particular, all excluded minors of 2-sums of uniform matroids;*
- (5) *The Vámos matroid is 1-locked;*
- (6) *\mathcal{L}_1 contains strictly the class of 2-sums of uniform matroids.*

4 Conclusion

We have given a new system of axioms for defining a matroid based essentially on locked subsets. We have proved that MIP and TSD are reducible to GI for polynomially locked classes of matroids. We have given some large classes of polynomially locked matroids. Future investigations can be characterizing partially or completely polynomially locked matroids.
